Ecological Genomics Ecology And The

Ecological genomics is trans-disciplinary by nature. Ecologists have turned to genomics to be able to elucidate the mechanistic bases of the biodiversity their research tries to understand. Genomicists have turned to ecology in order to better explain the functional cellular and molecular variation they observed in their model organisms.

We apply ecological genomics approaches to answer fundamental questions about adaptation and species survival. Our research interests fall into three themes, and are centred on tree species from the Indo-West Pacific region, with a focus on East and Southeast Asia: Adaptation of tropical trees to physiological stress

Ecological genetics is the study of genetics in natural populations. Traits in a population can be observed and quantified to represent a species adapting to a changing environment. This contrasts with classical genetics, which works mostly on crosses between laboratory strains, and DNA sequence analysis, which studies genes at the molecular level. Research in this field is on traits of ecological significance—that is, traits related to fitness, which affect an organism's survival and ...

Metagenomics or microbial environmental genomics provide a different tool that gravitates around the habitat rather than the species. Such tool could be just the right way to complement 'organismal genomics'. Its potential to advance our understanding of microbial ecology and prokaryotic diversity and evolution is discussed.
